01 | Baseline Performance

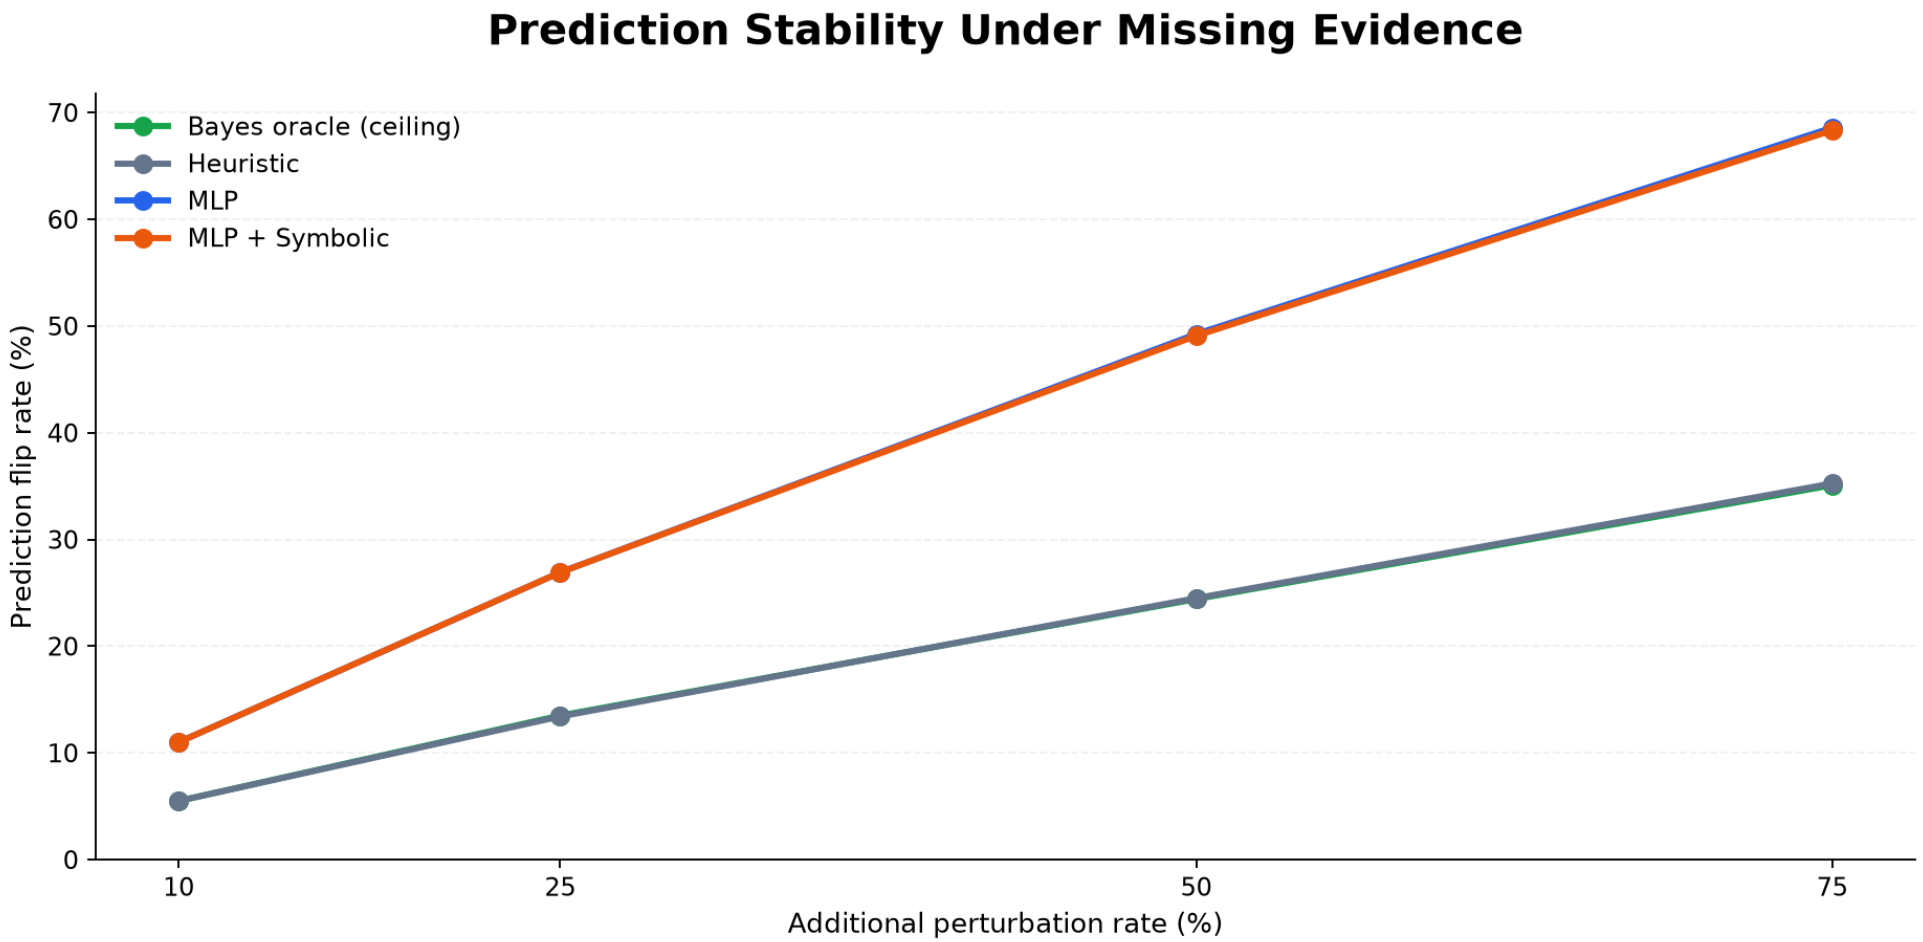

MLP slightly outperforms the heuristic baseline in accuracy and macro-F1.
Soft symbolic fusion does not improve baseline accuracy.

02 | Missing Evidence - Accuracy

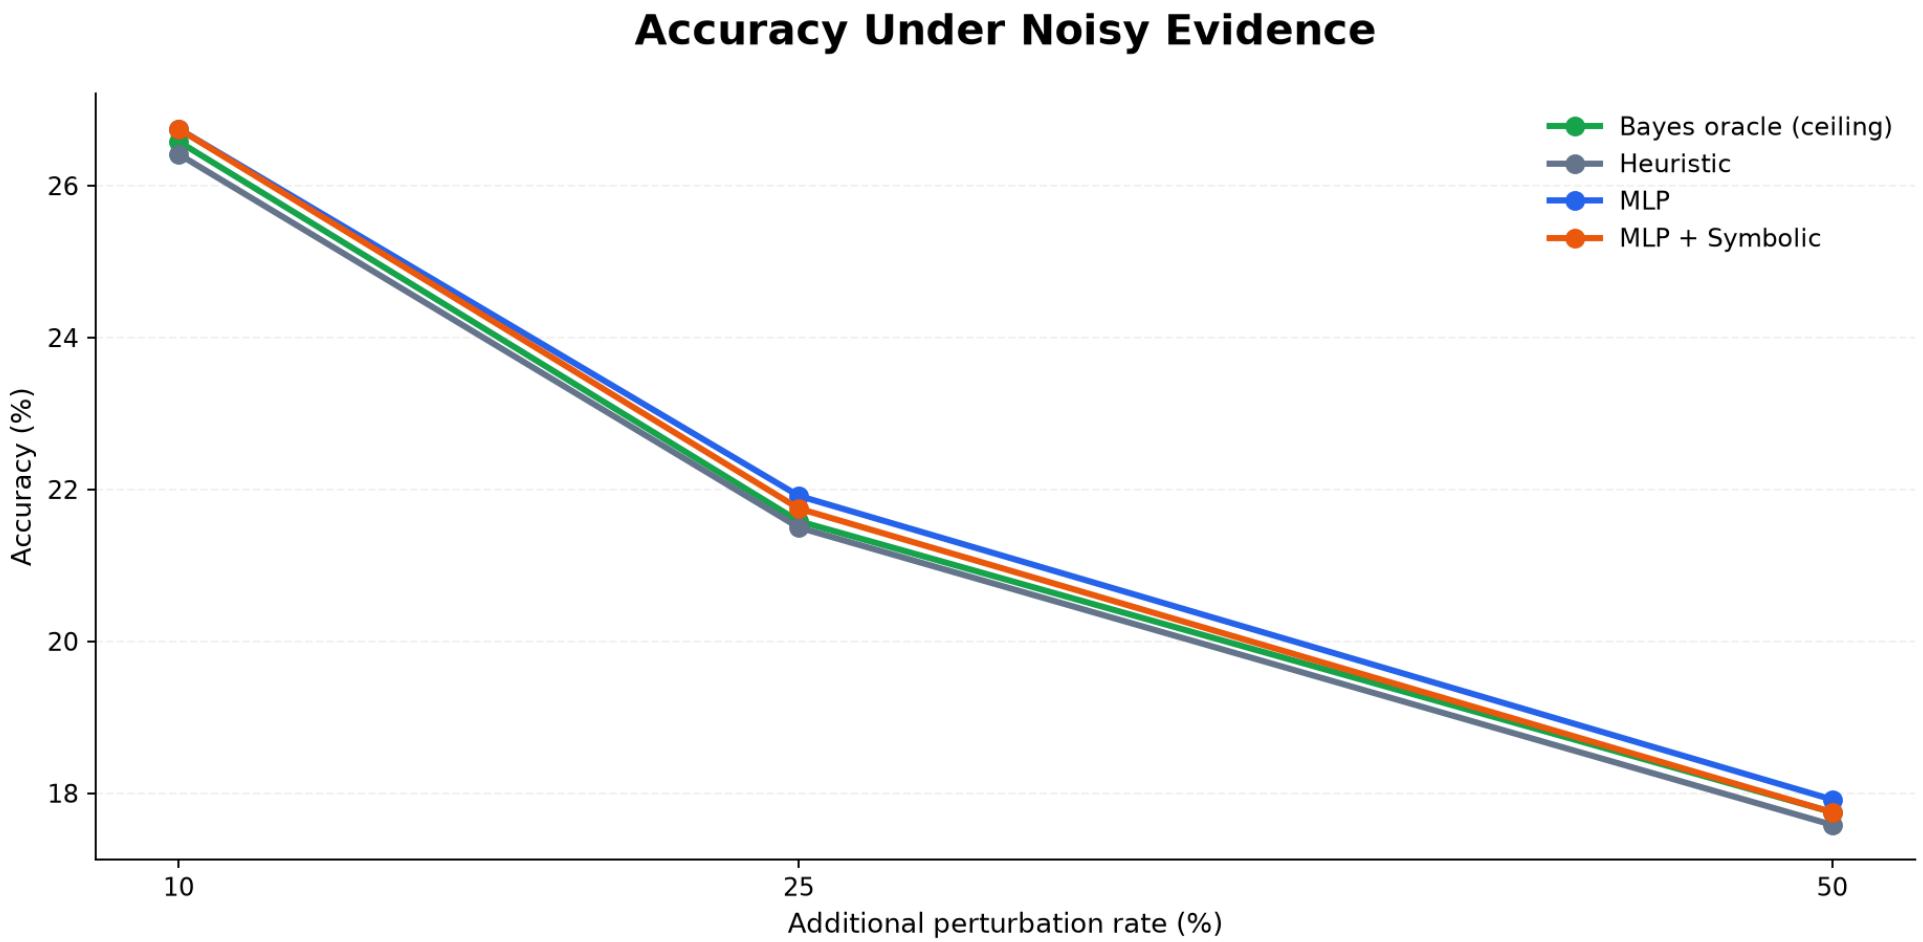

Accuracy decreases as more observed evidence is removed.
All three methods approach similar accuracy at high missingness.

03 | Missing Evidence - Stability

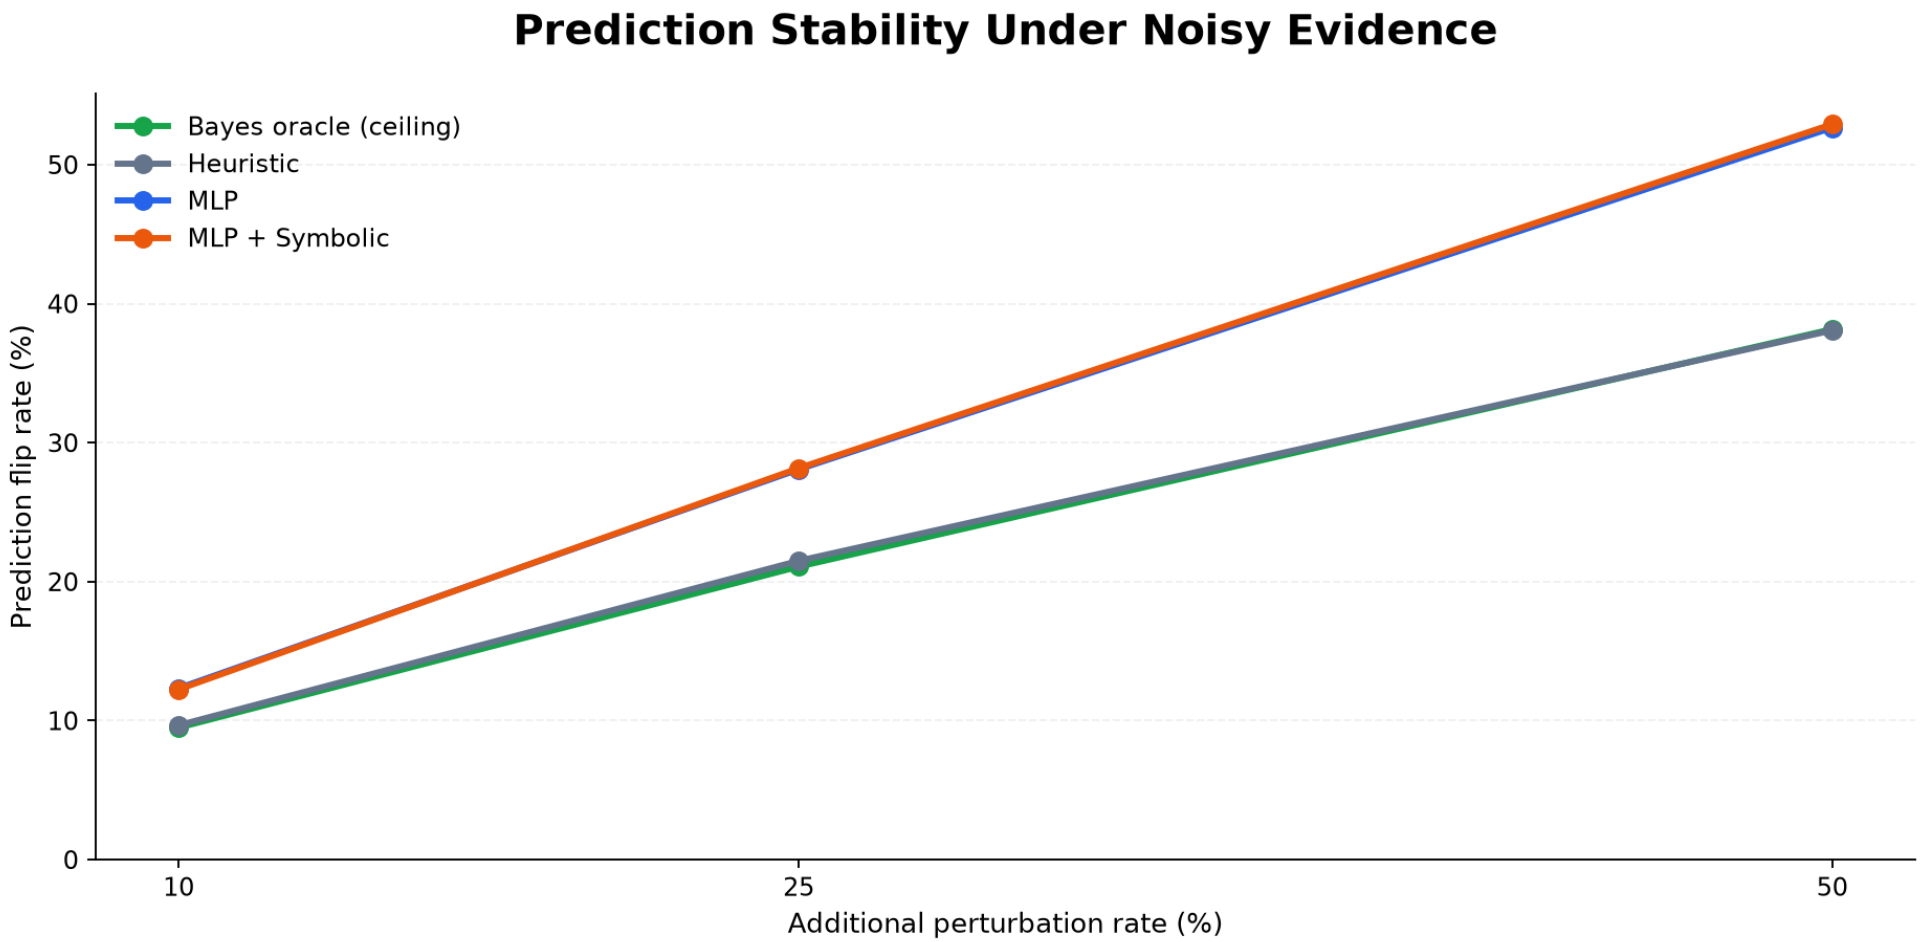

The heuristic baseline changes predictions less frequently than MLP.
Lower flip rate alone does not guarantee higher accuracy.

04 | Noisy Evidence - Accuracy

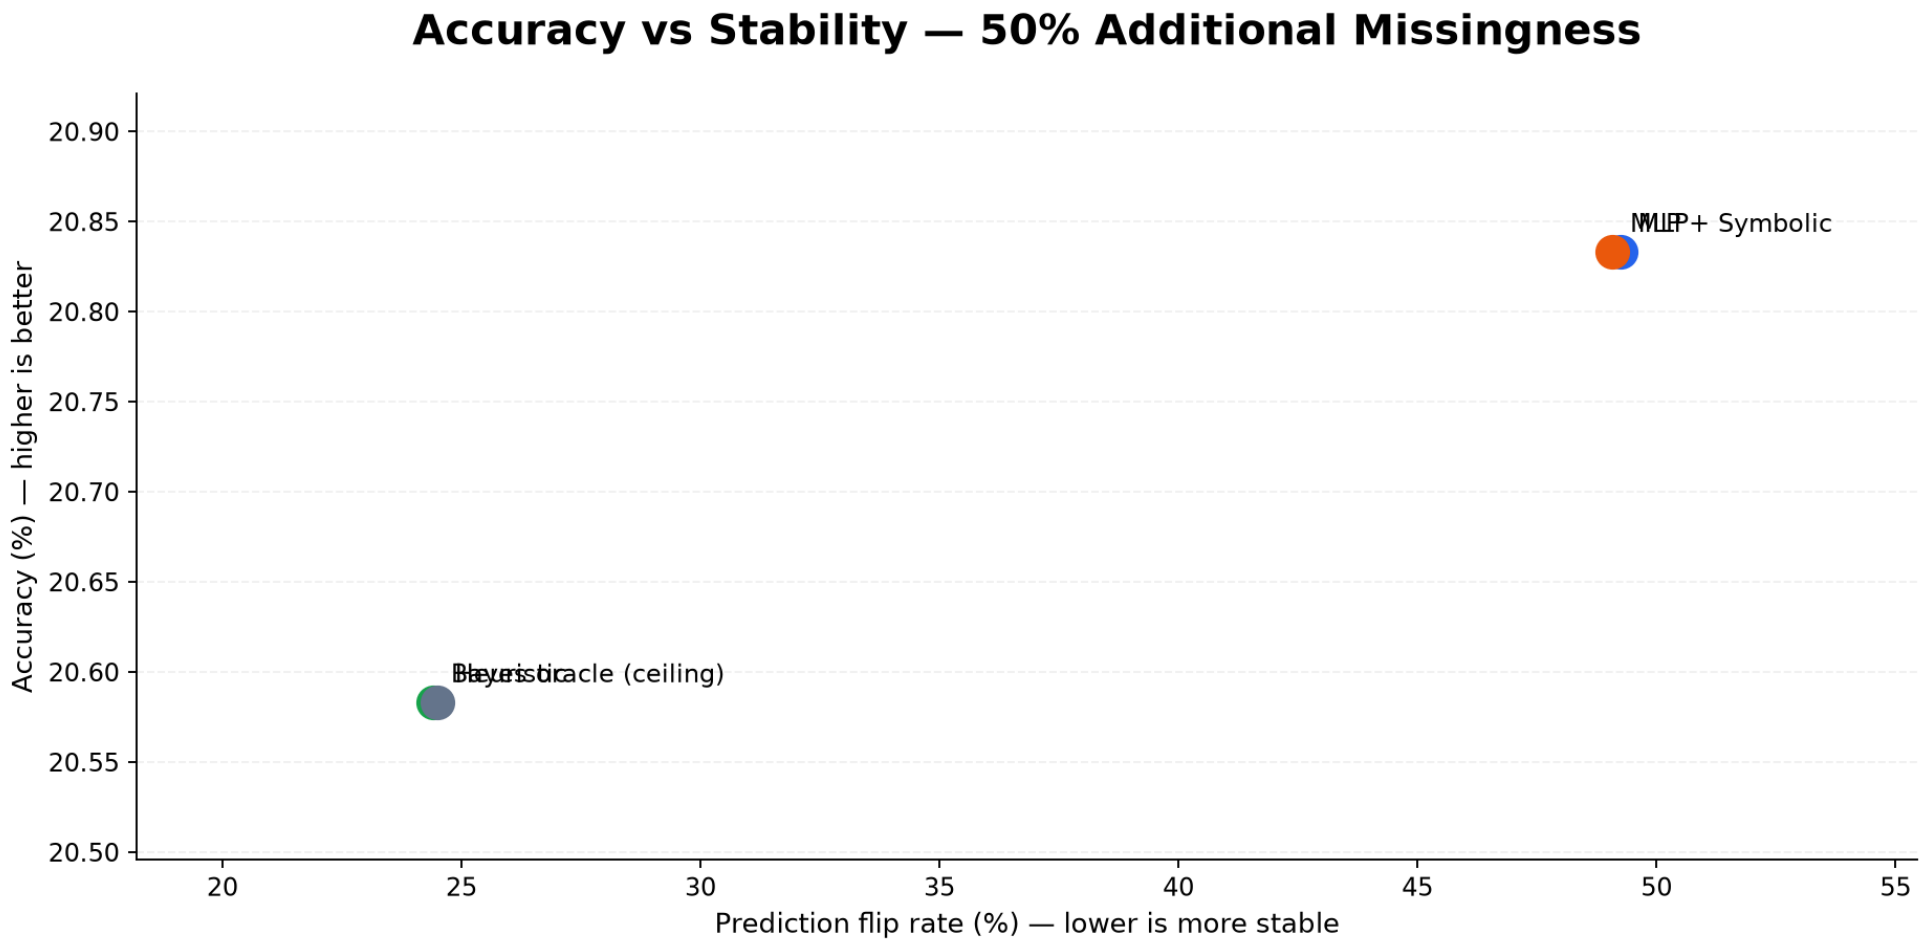

Random corruption of observed probe values reduces accuracy.
Soft symbolic fusion shows no consistent improvement over MLP.

05 | Noisy Evidence - Stability

MLP predictions are more sensitive to noisy evidence than heuristic predictions.
Fusion produces a similar sensitivity profile to the neural baseline.

06 | Accuracy vs Stability

At 50% additional missingness, accuracy is similar across models.
The heuristic baseline exhibits substantially fewer prediction flips.
